HOTS

Why is mushroom rock eroded more at the bottom than the top?

Zeugen

Zeugen is a landscape of alternate horizontal ridges and furrows made by the action of wind abrasion. It may be as high as 30 m height.

4.9.2 Depositional Landforms of Wind

1. Sand dunes

Dry hot deserts are good places for sand dune formation. According to the shape of a sand dune, there are varieties of sand dune forms like Barchans, Seif dune, etc. The barchan is one of the classic desert landforms. It is a crescent-shaped dune with the horns of the crescent stretching out in the leeward direction.

Barchan dunes may reach more than 27 meter in height.

Seif dunes are long ridges of sand. In general they are aligned in the direction of the prevailing wind. The slip face of seif dunes are probably formed by eddies. The depressions between seif dune ridges are swept clear of sand by the winds. The ridges run for long distances, sometimes several kilometres.

Figure 4.26 Sand Dunes

2. Loess

In several large areas of the world, the surface is covered by deposits of wind transported silt that has settled out from dust storms over many thousands of years. These depositions are called as Loess.

3. Pediplains

When the high relief structures in deserts are reduced to low featureless plains by the activities of wind, they are called as Pediplains.

4.10 Waves (Coast)

Horizontal movement of sea water caused by the wind, rotation of the earth, etc., are called waves.

4.10.1 How do Waves Erode?

Waves carry out the erosive work in the following ways.

1. **Abrasion**: The waves striking against the coast with eroded materials is called abrasion. Abrasion is also called as the corrasion.
