

Square method: The square method is the most common method to measure area. In this method, the area to be measured is covered by squares by placing a sheet of graph paper beneath the map on an illuminated tracing table or by tracing the area onto the graph sheet. The squares pertain to a scale.

Example:1

Calculate the area of the given map whose scale is 1 centimetre = 1 kilometre cover the given area with a set of squares of side.

Area of 1 small square = 1 km^2

Step 1: Count the number of full squares first = 10 (shaded blue) 1 small square = 1 cm^2

Step 2: Next, count the numbers of the fractional squares

¾ square (yellow) = 4,

½ square (green) = 2 and

¼ square (pink) = 10

Step 3: Calculate the total number of squares 10

$10 \times 1 = \mathbf{10}$,

Number of 3/4 square

$4 \times 3/4 = \mathbf{3}$

Number of 1/2 squares

$2 \times 1/2 = \mathbf{1}$ and

number of 1/4 squares

$10 \times 1/4 = \mathbf{2.5}$

Step 4: Add all these values

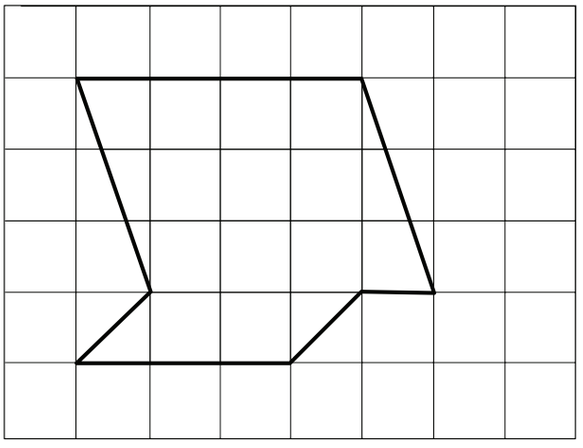

($\mathbf{10 + 3 + 1 + 2.5 = 16.5}$ squares)

Step 5: Multiply 16 with the scale of the map

16.5 × 1 km^2 = 16.5 km^2

Hence the area of the given place is = 16 square Km.
