- **A valley** is a long depression with steep slope formed by the vertical erosion of the river within the stretch of upland. The contours bend sharply across the river in a 'V' shape with the apex pointing towards higher elevations.
- **Spurs** are projection of land from higher to lower ground. Contours bend smoothly with the apex of the 'V' pointing towards lower ground.
- **A waterfall** occurs when there is a sudden difference in height of the river valley.A **waterfall** is a place where water flows over a vertical drop or a series of steep drops in the course of a stream or river. It is represented by contours meeting at a same point on the hill slope. The difference between the value of the highest and the lowest contour touching the same point gives the height of the waterfall.
- **A cliff** is a steep sloped exposure of a valley or coast. If it is near sea we call it sea cliff.
- **Gorge** is a very steep valley at higher elevations formed by river erosion. It can be identified by closely converging contours in the river course.
- **A volcano** is represented by closed contours with the innermost contours having lesser values than the surrounding, denoting the crater depression.
