Steps for preparing Analysis table:

We prepare a grouping table with 6 columns

(i) In column I, we write down the given frequencies.

(ii) Column II is obtained by combining the frequencies two by two.

(iii) Leave the Ist frequency and combine the remaining frequencies two by two and write in column III

(iv) Column IV is obtained by combining the frequencies three by three.

(v) Leave the Ist frequency and combine the remaining frequencies three by three and write in column V

(vi) Leave the Ist and 2nd frequencies and combine the remaining frequencies three by three and write in column VI

NOTE

In discrete or continuous series, an error of judgement is possible by finding y inspection. In these cases, where the difference between the maximum frequency and the frequency preceeding or succeeding is very small and the items are heavily concentrated on either side, under such circumstance the value of mode is determined by preparing grouping table and through analysis table.

Mark the highest frequency in each column. Then form an analysis table to find the modal class. After finding the modal class use the formula to calculate the modal value.

Example 5.26

Calculate mode for the following frequency distribution:

Size	0-5	5-10	10-15	15-20	20-25	25-30	30-35	35-40
Frequency	9	12	15	16	17	15	10	13
