Armstrong (who developed a resonant oscillator circuit for radio frequency work) and Marconi (the 1909 Nobel laureate in Physics, who in the year 1901 established the first transatlantic radio contact). A ham radio operator is a radio enthusiast who by virtue of his fascination towards wireless communication technology enables himself to establish his own two way radio station and communicates around the world for the sheer joy, thrill and excitement involved in successfully establishing radio contacts around the world.

SPEED PRACTICE – 23:

SPEED PRACTICE - 23 Time - 15 Minutes

Type the following in double line spacing with a margin of 10 degrees:-

Living on the earth is rather like being at the bottom of a sea hundreds of miles deep on the floor of a great ocean of air that surrounds our planet and without which nothing could live. Without the atmosphere there would be no people or animals, birds or fishes, trees or plants. There would be no weather, winds or rain. And there would be no blue sky, no rosy sunsets or dawns. Fire would be impossible without air, for burning is the union of oxygen with whatever is burned. Nor would there be any noise, which is the vibration of air waves against our ear-drums.

By day the atmosphere serves as a great sunshade. It protects the earth from the full force of the sun by absorbing most of its harmful radiation. But for the atmosphere the day-time temperature would rise to 230 degrees F. hotter than boiling water. By night, the air acts like a giant green house. It imprisons the heat collected during the day and prevents it from spreading into space. Otherwise the temperature at night would plunge to 300 degrees F. far colder than we could stand. Finally the atmosphere catches and burns up by friction, practically all the million meteors that fall each day from outer space into the earth's field of gravity. If all these meteors actually landed here, the earth's surface would be pitted and dented like the face of the moon which has no atmosphere to stop them. It is not true that the air gets gradually colder the higher up you go. It does this up to a height of about seven miles.

It is the lower layers of the atmosphere are warmed by heat radiated from the ground. In the stratosphere the next layer up the temperature remains almost the same, but it drops to a chilly 40 degrees F. at about eighteen miles. There the temperature begins to rise because of certain gases that absorb heat directly from the sun. When these gases disappear at about fifty miles, the temperature drops right down to 117 degrees F. After that it rises steadily, reaching 4,118 degrees F. at 250 miles. Even if we could live in these amazing temperatures, we could not feel them. When we feel warmth on a summer's day, it is because our skin is being bombarded by countless air particles. Our sensations of heat or cold depend on how fast these particles travel.
