Cells are Classified as Dry and Wet Cells.

4.1.1 Dry Cell

Dry cell is one that has a paste (or) gel electrolyte. It is semi sealed and can be used in any position. Nowadays the term 'Dry cell' refers to a cell that can be operated in any position without leakage.

4.1.2 Wet Cell

Wet cells are cells that must be operated in an upright position. These cells have vents to allow the gases generated during charging or discharging to escape. The most common wet cell is the Lead-Acid cell.

4.1.3 Primary Cells

Primary cells are those cells that are not rechargeable. That is, the chemical reaction that occurs during discharges is not easily reversed. When the chemicals used in the reactions are all converted, the cell is fully discharged. It must then be replaced by a new cell.

Example:-

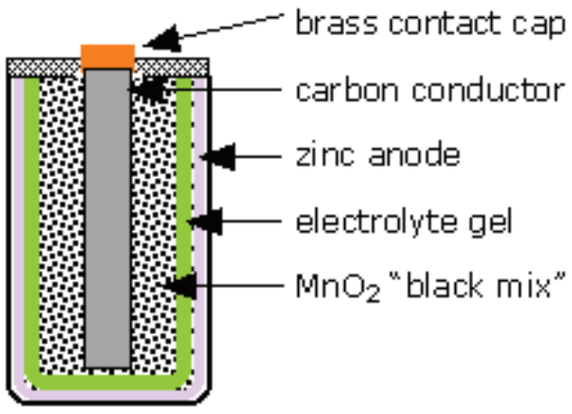

Voltaic cell, Leclanche cell, Alkaline cell, Mercury cell, Lithium cell.

4.2 DRY CELL

The most common and the least expensive type of a dry cell battery in the Zinc-carbon type as shown in figure 4.2.

Fig 4.2 *Dry Cell.*

The Zinc-carbon consists of a zinc container which acts as the negative electrode. In the center, carbon rod which is a positive electrode is present. The electrolyte takes the form of a moist paste, made up of a solution containing ammonium chloride. As with all primary cells, one of the electrode becomes decomposed as part of chemical reaction. As a result, cells left in equipment for long periods of time can rupture, spilling the electrolyte and causing damage to the other parts.

Zinc-carbon cells are produced in common standard sizes. These include 1.5v AA, C, D cells.

(AA-pen type cell, C-minimum size, D-large/Economy size.)
