- Heat cramps are associated with cramping in the abdomen, arms and calves. This can be caused by inadequate consumption of fluids or electrolytes.

Treating Heat Cramps

Identify when you have a heat cramp.

Heat cramps are painful muscle spasms that result from dehydration, typically due to exercising or working in hot environments.Heat cramps are not simply caused by heat or being in a hot environment, as the name might suggest. Intense sweating from the exertion results in a loss of both fluid and the electrolytes (salt) needed for proper muscle function.

Stop exercising. Heat cramps are not something you "push through" during exercise. That are body's way of telling that it needs a break. The first step to treat a heat cramp is to cease the exercise routine or activity that led to the cramp.

Rest in a cool environment

Heat cramps are most commonly associated with overexerting yourself in the summer heat. If this is the case, get out of the sun as well. Find a cooler spot in the shade or indoors and give yourself time to rest and cool down.

- You can help your body cool down by applying a wet towel to the back of your neck.

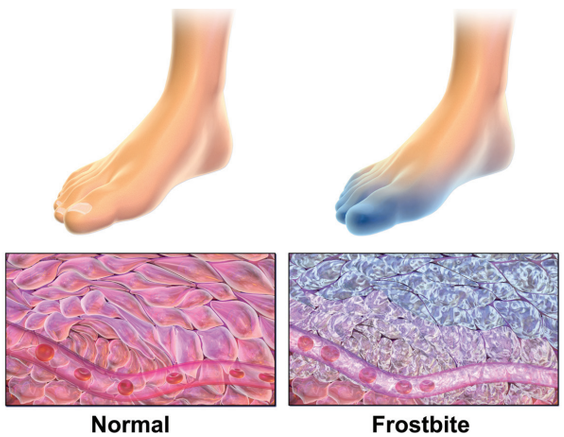

Drink plenty of fluids

The cramp is a response to dehydration and loss of electrolytes, so you should also drink lots of fluids while you rest, preferably a sports drink (Gatorade, etc.) or an electrolyte beverage such as Pedialyte. Sports drinks with 25 – 200 mg of sodium are best.

- Clear juice is also an option that will provide both the fluids and electrolytes you need.
- If all you have available is water, then dissolve a quarter or half teaspoon of regular table salt into one quart of water.It might not taste as good as a sports drink, but it will do the trick.
- Perform gentle stretches to the affected muscle group.
- Help make the cramp go away more quickly by gently stretching the muscle group. Use range-of-motions stretches rather than intense stretches. This will help reduce the spasming and pain in the muscles.

7.14 FROST BITE

This condition usually occurs in freezing and often dry and windy conditions.Frost bite occurs when the ears, nose, chin, hands and feet are exposed to prolonged or intense cold. Frostbite is often accompanied by hypothermia.

DO NOT put affected part by direct heat, it is danger of it refreezing.
DO NOT warm the part very fast.
