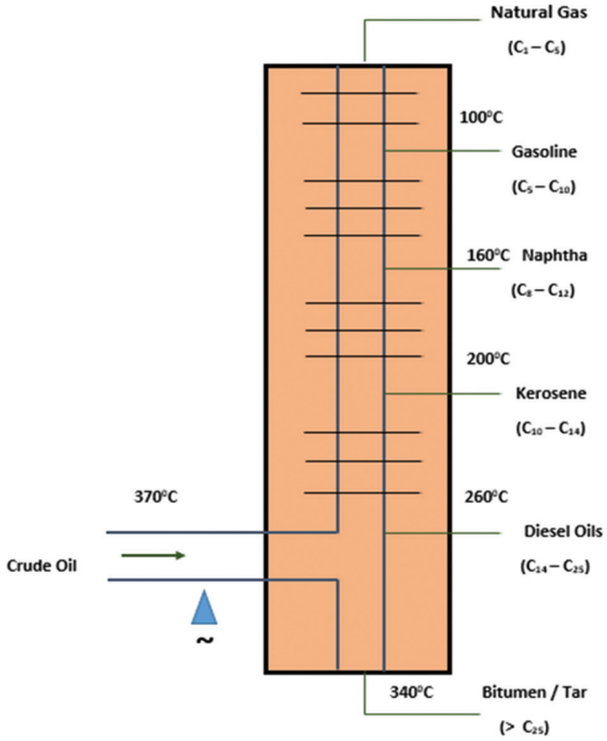

Figure 3.1.2.1(a) Line Diagram of Distilation Process of Various Components.

In petrol have Carbon 79.5% to 87.1%, Hydrogen 11.5% to 14.8%, Sulphur 0.1% to 3.5%, Oxygen and Nitrogen 0.1% to 0.3% and the following special properties are must be in petrol.

1. **Volatility:** Volatility refers to the tendency of fuel to vaporize from liquid state to gaseous state. Boiling Point is an indicator of volatility. Higher the boiling point, the less volatile the fuel. A highly volatile fuel is more likely to form a flammable. Petrol should be sufficiently volatile to form combustible vapor. Petrol must be sufficiently volatile to evaporate at low temperature, for easy starting of the engine, but not so volatile as to evaporate in fuel lines, causing vapor lock and thus preventing flow of liquid fuel.
