b. Analytical centrifugation: This technique is used to study the characteristic feature of a pure macromolecule. Specially designed rotors and detector systems are needed to continuously monitor the process of sedimentation of the material in the centrifugal field.

i. Differential centrifugation:

Differential centrifugation is based on the difference in the sedimentation rate of the particles of different size and density. It is used for the isolation of sub-cellular organelles. The centrifugal force is proportional to the radius of the centrifugal head and to the square of angular velocity. Therefore, it is possible to use small rotor heads at very high speeds.
