

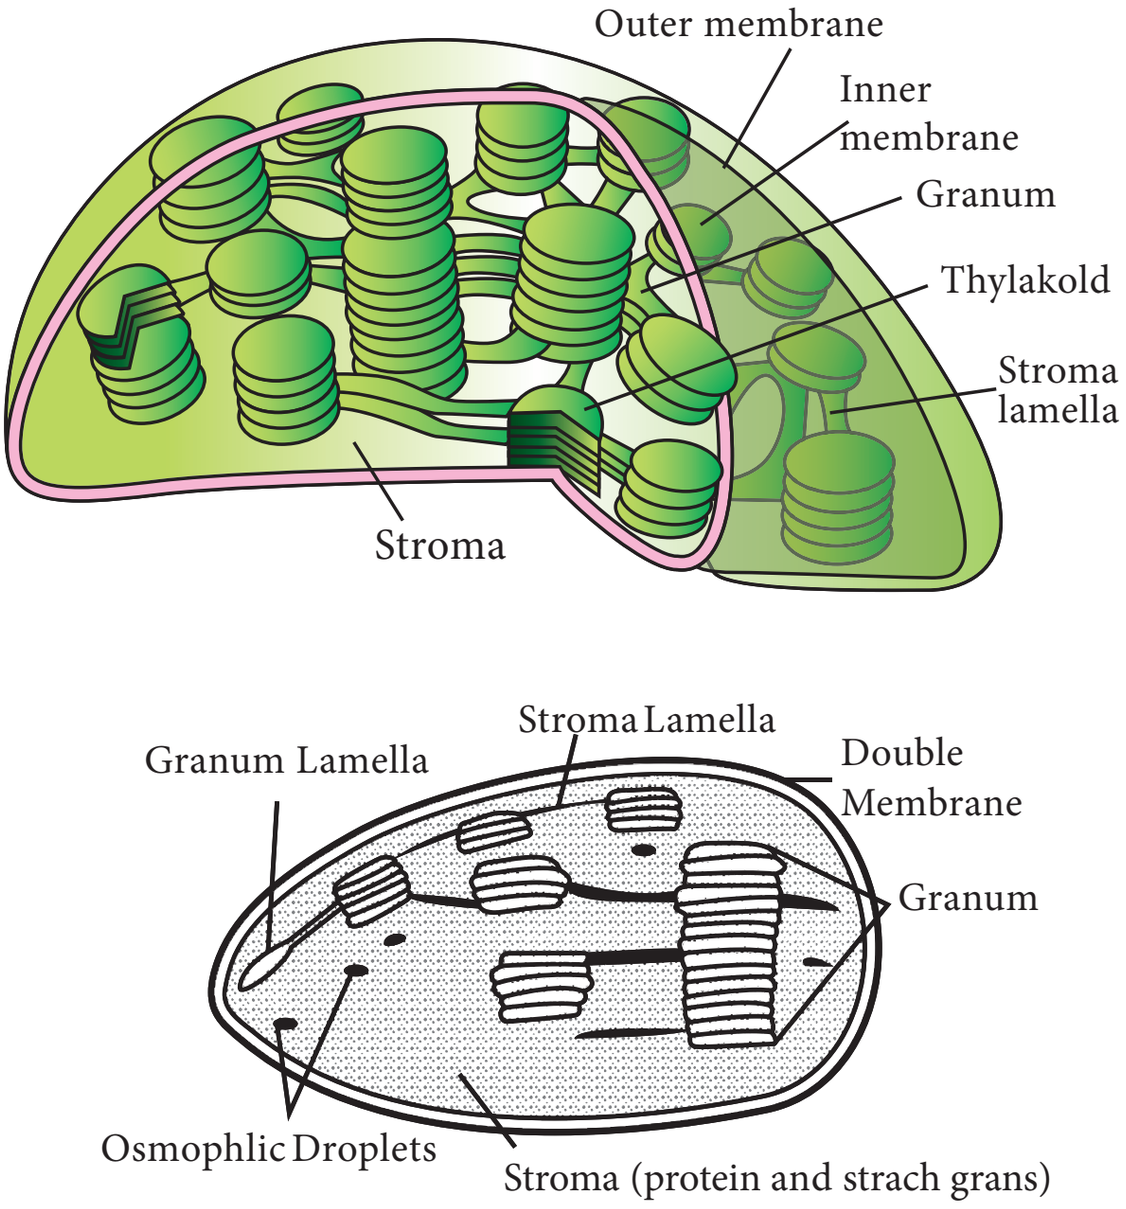

Figure 1.12 A schematic diagram of chloroplast

The thylakoids in chloroplasts contain chlorophyll and carotenoid pigments which are responsible for trapping light energy essential for photosynthesis. Chloroplasts develop in the parts of a plant, such as leaves, in which light gathering and photosynthesis will occur. Plants that are grown in the dark do not develop chloroplasts but instead develop a different type of plastid in their leaves. Chloroplasts develop into chromoplasts when tomatoes ripen from green to red and when green leaves of deciduous trees turn red orange or yellow.

Functions of chloroplast

- Chloroplasts function as the food producers of the cell and every green plant in the planet is working to convert the solar energy into sugars.
